1 Introduction

When we think about building a sampling surface piece by piece from the inclusion zones of individual “Stem” objects, we assign the appropriate attribute value to each grid cell within the inclusion zone for an object, with zero values elsewhere, and then algebraically add this grid layer to the overall “Tract” grid. Thus, we “heap up” the inclusion zone density of the grid cells within the tract, which in the end is a discrete estimate of the sampling surface.

This class allows us to do the geometry associated with the individual “InclusionZone” objects for each “Stem” object in the population. Recall that an “InclusionZone” object has both an

*Phone: (603) 868-7667; Fax: (603) 868-7604.

“ArealSampling” and “Stem” subclass as slots in its definition. For example, an object of subclass “standUpIZ” would have both a “circularPlot” class object and a “downLog” object making up the overall bounding box. There are methods for the “InclusionZoneGrid” class objects that work with each type of “InclusionZone” object. In general, the methods are all of the name `izGrid`, whose signature objects initiate the appropriate method.

In the following, we show some general constructs of the class with respect to individual subclasses of “InclusionZone” objects they are based on. Graphics play a big role in getting the idea, and each class is a little different, so several illustrations are presented. Whether a surface within an inclusion zone is constant or variable height depends on the sampling method. For example, what we term “canonical” perpendicular distance sampling (PDS) has constant height surfaces, while “omnibus” PDS has surfaces of varying height. In addition, the somewhat odd, but interesting “full chainsaw” method where the entire sausage-based inclusion zone is filled with variable-height individual chainsaw estimates is also shown.

2 The “InclusionZoneGrid” Class

The base class is defined with the slots...

```
R> showClass('InclusionZoneGrid')
```

```
Class "InclusionZoneGrid" [package "sampSurf"]
```

```
Slots:
```

Name:	description	iz	grid	data	bbox
Class:	character	InclusionZone	RasterLayer	data.frame	matrix

```
Known Subclasses: "csFullInclusionZoneGrid"
```

2.1 Class slots

- *description*: Some descriptive text about this class.
- *iz*: An object of one of the “InclusionZone” subclasses.
- *grid*: A “RasterLayer” object.
- *data*: A data frame holding the values for each of the per unit area estimates available in the “InclusionZone” object in the columns, with rows for grid cells.

- *bbox*: The overall bounding box for the object, which includes the inclusion zone and the “Stem” subclass object plus the grid. Sometimes the inclusion zone itself includes the stem, but other times it does not.

I made a decision when designing this class to go with the slots above. A possible problem with this design is the very real possibility of people misunderstanding the class structure. This is because the grid object has values of just zero and NA. In other words, it does not store the per unit area estimates within the cells of the grid. These are stored in the **data** slot of the object and can be swapped into the **grid** slot object with a simple command...

```
R> x@grid = setValues(x@grid, x@data[,estimate])
```

where **x** is the “InclusionZoneGrid” object. Unfortunately, again this may cause problems with misunderstanding, down the line as it is going to have to be done whenever one wants an underlying **grid** with real per unit area values. An alternative to this would have been (and still could be) to use a “RasterStack” or “RasterBrick” class for the **grid** slot. This would obviate the need for the **data** slot. But it also has drawbacks, because these objects seem to be designed more for map layers that are algebraically related. I did not want people unwittingly summing layers within this object, for example, and thereby adding things like number of stems and cubic volume. I may reconsider this, however, as the latter approach does have its benefits (even though it takes more storage). Another potential drawback of the latter is that there seems to be no way to name the “layers” within a brick or stack, they simply get assigned numbers, so we’d again have to keep track of this with program code.

When plotting the object, the above substitution gets made automatically, one simply has to specify the desired attribute to plot in the **estimate** argument to the **plot** method. For example, to plot the coverage area surface, specify **estimate = 'coverageArea'** in the plot command. The default is to plot the surface for volume.

3 Example: The “standUpIZ” Class

Refer to the “InclusionZoneClass” vignette for more information on this class.

Here we demonstrate the construction of an “InclusionZoneGrid” object from an object of class “standUpIZ”.

```
R> tra = Tract(c(x=100, y=100), cellSize = 0.5, units = 'metric',
+           description = 'a 1-hectare tract')
R> btr = bufferedTract(10, tra)
R> btr
```

```
-----  
a 1-hectare tract  
-----
```

```
Measurement units = metric
```

```
Area in square meters = 10000 (1 hectares)
```

```
class      : bufferedTract  
dimensions : 200, 200, 1 (nrow, ncol, nlayers)  
resolution : 0.5, 0.5 (x, y)  
extent     : 0, 100, 0, 100 (xmin, xmax, ymin, ymax)  
projection : NA  
values     : in memory  
min value  : 0  
max value  : 0
```

```
Buffer width = 10
```

```
R> dlogs = downLogs(1, container=btr@bufferRect, buttDiam=c(30,40),  
+                  logLen=c(6,10), topDiams=c(0,0.5), solidTypes=c(2,4),  
+                  vol2wgt=20.1, wgt2carbon=0.5)  
R> sup = standUpIZ(dlogs@logs$log.1, 3)  
R> izgSU = izGrid(sup, btr)
```

Here we have created a 200 by 200 cell raster grid in the form of a “Tract” object, having resolution of 0.5 meters, yielding spatial extents of 100×100 meters, (i.e., a 1 hectare tract), with origin at (0,0) meters. Then we create a buffered tract object with a 10-meter buffer, and drew a single random “downLog” object within the tract, which we used to create an object of class “standUpIZ” with a 3 meter radius for the circular plot. Finally, using the “standUpIZ” object and the underlying buffered tract grid, we create the “InclusionZoneGrid” object that will be aligned to the tract grid.

Now, in the following example we plot this object...

```
R> plot(izgSU)
```

There are two ways to generate the object which depend on how one wants the underlying grid developed. The argument `wholeIZ` determines how this is done, and defaults to `TRUE`. We can see in Figure 1 that the underlying grid covers the entire inclusion zone plus the down log object. If we wanted to just cover the inclusion zone only, with a minimal bounding grid we would do the following (Figure 2)...

```
R> izmbgSU = izGrid(sup, btr, wholeIZ=FALSE)  
R> plot(izmbgSU, gridCenters=TRUE)
```

Figure 1: An “InclusionZoneGrid” object based on a “standUpIZ” object.

4 On Design Motivation

Having now seen that we can make the grid object cover more than just the inclusion zone if applicable (i.e., the stem lies partially outside it), we can delve a little more into the motivation for this class. First, it is entirely possible to do approach the sampling surface construction in a more brute-force manner in one of at least two ways...

1. Brute-force method 1...

- Make an exact duplicate of the tract and assign zeros to all its values.
- Then overlay the inclusion zone onto this to get a mask.
- Assign the per acre values to the cells within the masked inclusion zone and zero outside.
- Algebraically add this layer to the base tract and repeat for all stems.

2. Brute-force method 2...

Figure 2: A “InclusionZoneGrid” object based on a “standUpIZ” object where only the actual inclusion zone is covered by the bounding grid, and grid cell centers are plotted as an option.

- Use the `rasterize` function within “raster” with `overlap='sum'` on the “InclusionZone” objects to sum them into the base tract grid.
- Repeat for all stems.

The problem with each of these approaches, even though they work, is the time it takes to implement them. In each case they are working on the entire tract and take significantly more time to do the accumulation than overlaying onto the smaller grid within the “InclusionZoneGrid” class. This is compounded if the tract is large, or the resolution is small, which we want usually for better estimates. This, along with the thought that perhaps the following approach is simpler to understand because one can see the individual surface components graphically, is why I elected to go this route.

In slightly more detail, the steps in accumulating the surface under the “InclusionZoneGrid” scheme are...

1. Create an “InclusionZoneGrid” object.
2. Expand its grid to the extent of the tract.
3. Add this expanded grid to the tract surface.
4. Repeat for all stems.

Conceptually it is similar to the other approaches except that the actual overlay is done on a minimal bounding grid for the object, and therefore is much faster. Expanding the grid mask in the “InclusionZoneGrid” object takes little effort, and adding it is the same in all steps.

5 Example: The “sausagesIZ” Class

Using the same grid and tree as above for an example with sausage sampling, we have...

```
R> saus = sausageIZ(dlogs@logs$log.1, 3)
R> izgSAUS = izGrid(saus, btr, wholeIZ=FALSE)
R> plot(izgSAUS)
```

Notice in Figure 3 that whether we specify using the whole inclusion zone or not is immaterial for sausage sampling, because the entire log is always included within the zone. Also note that the minimal bounding grid is always calculated to include the entire zone, even if there is an extra cell padding all around. This is trivial and is necessary for making sure all cells within the zone get assigned the correct value.

6 Example: The “chainSawIZ” Class

Here are a couple similar examples for the “chainSawIZ” class. Gove and Van Deusen (2011) discuss how the inclusion zone is really just a point, the center point of the circular plot that intersects the downed log, rather than the plot itself. Therefore, under this method, we assign the sampling surface value to only that one grid cell that contains the circular plot center point.

```
R> csaw = chainSawIZ(dlogs@logs$log.1, plotRadius = 3,
+                   plotCenter = coordinates(dlogs@logs$log.1@location)[1,] + c(1,-1))
R> izgCSaw = izGrid(csaw, btr, wholeIZ=FALSE)
R> izgCSaw
```

Figure 3: A “InclusionZoneGrid” object based on a “sausageIZ” object showing that the stem and inclusion zone are covered by the bounding grid.

Object of class: InclusionZoneGrid

Max.	68.06	353.7	1911	1424	453.2	1368	684

Encapulating bounding box...

	min	max
x	47.785021	54.311248
y	16.620067	23.241805

```
R> plot(izgCSaw, gridCenters=TRUE)
```

Figure 4 shows the concept for a given circular plot location showing volume in cubic meters per hectare. This clearly shows that only one grid cell gets assigned a value. Note in the above that there is only a single grid cell in the object comprising the “InclusionZoneGrid”.

We can also show the minimal bounding grid that includes the whole circular plot plus the log, as we have done in previous examples. Figure 5 presents this graphically.

```
R> izgCSaw = izGrid(csaw, btr, wholeIZ=TRUE)
R> plot(izgCSaw, gridCenters=TRUE, estimate='Density',
+       showPlotCenter=TRUE, izCenterColor = 'white')
```

As with the other figures, the overall minimal bounding grid in Figure 5 has all grid cells other than the one at the center of the circular plot set to zero. Therefore, doing any subsequent map algebra will have no effect on the sampling surface using this enlarged grid. Showing this minimal bounding grid is more an effort to help illustrate the underlying concepts.

It is especially important to recognize that the center point of the circular plot does not necessarily lie at the center of any given grid cell. Depending upon the cell resolution used, this can make the placement of this respective cell look “off-center” with respect to the circular plot’s perimeter itself. It is only true that the center point falls somewhere within the inclusion zone grid cell, which could even be right on the edge. This is shown in Figure 5 where we use a white cross for the circular plot center, and is demonstrated below in terms of actual coordinates...

Figure 4: A “InclusionZoneGrid” object based on a “chainSawIZ” object showing that the inclusion zone is only a single point, and therefore is assigned to just one grid cell.

```
R> cpt = perimeter(csaw, whatSense='point') #circular plot centerpoint
R> cn = cellFromXY(izgCSaw@grid, cpt)      #cell number for plot center point
R> xy = xyFromCell(izgCSaw@grid, cn)       #cell center point
R> rbind(coordinates(cpt), xy)
```

```
      x      y
[1,] 51.311248 19.619689
[2,] 51.250000 19.750000
```

6.1 Snapping to the grid

As another example, suppose we wanted to develop a figure that shows essentially the same depiction as in Figure 5, but also including the overall sausage inclusion zone, and the plot center exactly

Figure 5: A “InclusionZoneGrid” object based on a “chainSawIZ” object showing the minimal bounding grid for the entire inclusion zone object; this also illustrates that the inclusion zone is only a single point, since only one grid cell is non-zero valued in terms of number of stems per unit area estimate.

aligned to a grid cell center. First we would make a “Tract” object that just holds the sausage inclusion zone object, the log, and the chainsaw inclusion zone object (complete with plot radius as in Figure 5). We can use the above steps to advantage to snap the plot centerpoint to the grid as follows...

```
R> xyExtent = c(x=10, y=10)
R> tra2 = Tract(xyExtent, cellSize=0.5)
R> dl = downLog(buttDiam=40, topDiam=15, logLen=6.5, logAngle=pi/4,
+             centerOffset=xyExtent/2 )
R> cn = cellFromXY(tra2, c(x=6.5, y=4.5))
R> (cpt = xyFromCell(tra2, cn)[,,drop=TRUE]) #coerce to vector from matrix
```

```

      x      y
6.75 4.25

```

```

R> izCS = chainSawIZ(dl, plotRadius = 2, plotCenter = cpt) #cell-based chainsaw iz
R> izgCS = izGrid(izCS, tra2)                               #and chainsaw iz grid object
R> hiz = heapIZ(izgCS, tra2)                                #heap it into the tract object
R> izSaus = sausageIZ(dl, plotRadius=2)                     #overall sausage inclusion zone

```

We use the `heapIZ` method in the above to “heap” the “InclusionZoneGrid” object for the single grid cell corresponding to the chainsaw method at that point, onto the tract. The rest of the idea behind this should be fairly standard and is covered in more detail in the vignettes for the respective objects.

To plot this object, we need to basically build it up from scratch, the result is shown in Figure 6...

```

R> plot(hiz, axes=TRUE, gridLines=TRUE)
R> plot(dl, add=TRUE)
R> plot(izSaus, add=TRUE, izColor=NA, lty='dashed', izBorder='gray40')
R> plot(izCS, add=TRUE, izColor=NA, showPlotCenter=TRUE,
+       izCenterColor='white', ltyBolt='solid')

```

7 The “csFullInclusionZoneGrid” Class

Gove and Van Deusen (2011) describe a certain protocol for the chainsaw method that leads directly to the sausage method. They also show by simulation how the chainsaw method is biased for whole-log attributes, because the full inclusion zone for the log is the sausage zone under this particular protocol. To show this, every grid point within the sausage inclusion zone has to be estimated individually with its midpoint acting as the center of the circular plot, and then applying the chainsaw method to that plot. Again, this is repeated for every grid cell within the sausage inclusion zone.

This necessitates a new class, actually a subclass of “InclusionZoneGrid” with one extra slot, and some more validity checking, as well as a new constructor for the objects. The extra slot is just used to store the result of *each* “chainSawIZ” object applied to each of the internal inclusion zone grid cells.

The class is defined with the slots...

```

R> showClass('csFullInclusionZoneGrid')

```

Figure 6: A built-up plot showing not only the “InclusionZoneGrid” object for one cell of the chainsaw method, but also the sausage object inclusion zone as would be determined by protocol 1 of Gove and Van Deusen (2011).

Class "csFullInclusionZoneGrid" [package "sampSurf"]

Slots:

Name:	chiz	description	iz	grid	data
Class:	list	character	InclusionZone	RasterLayer	data.frame

Name:	bbox
Class:	matrix

Extends: "InclusionZoneGrid"

7.1 Class slots

- *chiz*: This is a list object containing NAs for cells outside the inclusion zone, but containing the full set of “InclusionZoneGrid” objects corresponding to each grid cell within the inclusion zone. As mentioned above, the grid cell center is used as the center point of the circular plot that defines the chainsaw intersection with the log.

The nice thing about the subclass extension for this new object is that only one slot was added; therefore, all of the functions that work on “InclusionZoneGrid” objects will also work on objects of this new class “csFullInclusionZoneGrid”. These include the `print`, `show`, `summary`, and `plot` routines.

In addition, because each of the components of the list in `chiz` is of class “InclusionZoneGrid” (or NA), we can apply any of the methods for that class on the individual slots. For example, we can plot them as in Figure 4, and look at how the chainsaw method works as we step from one cell to the next, showing the intersections of the circular plots with the log.

7.2 Object Construction and Plotting

Now, object construction takes quite a while because it has to compute the chainsaw intersections, etc., for each internal sausage grid cell. So here we use an existing object to demonstrate the idea. In the following, we show how to make an object of class “csFullInclusionZoneGrid” using its constructor, but do not evaluate it (we use the existing object instead); the steps leading to its creation are also shown...

```
R> btLog = sampleLogs(1, buttDiam=c(30,40), sampleRect=buffTr@bufferRect,
+                   logLen=c(4,6), topDiams=c(0, 0.5) )
R> btLog = downLogs(btLog)
R> btLog = btLog@logs$log.1
R> btLog.sa = sausageIZ(btLog, 3)
R> btLog.izgsa = izGrid(btLog.sa, buffTr)
R> btLog.izgFCS = izGridCSFull(btLog.izgsa, buffTr)
```

where `buffTr` is essentially the same as `btr` used in the previous examples.

```
R> btLog.izgFCS
```

```
Object of class: csFullInclusionZoneGrid
```

```
-----
```

Full chainSaw-sausage inclusion zone grid object

InclusionZone class: sausageIZ
 units of measurement: metric

Grid class: RasterLayer
 Number of grid cells = 375
 Cell dimensions: (nrows=15, ncol=25)
 Grid cell values**...

	gridValues	Freq
1	0	245
2	<NA>	130

**Note: data slot values get swapped with zero-valued grid cells as necessary.

Per unit area estimates in the data slot (for cells inside IZ only)...

	volume	Density	Length	surfaceArea	coverageArea	biomass	carbon
Min.	0.02701	353.7	2.397	1.758	0.2131	0.5888	0.2944
1st Qu.	27.42000	353.7	498.400	459.900	146.0000	597.7000	298.8000
Median	77.31000	353.7	926.600	929.600	295.9000	1685.0000	842.7000
Mean	85.24000	353.7	942.400	972.500	309.1000	1858.0000	929.2000
3rd Qu.	143.30000	353.7	1387.000	1475.000	469.5000	3124.0000	1562.0000
Max.	186.50000	353.7	1935.000	2120.000	673.7000	4065.0000	2033.0000

Encapulating bounding box...

	min	max
x	61.0	73.5
y	61.5	69.0

One thing to note in particular, is that in the printed summary of the object above, the summary statistics vary here because the grid cells are composed of individual chainsaw estimates; this is not true for methods where the cells internal to the inclusion zone only take a single constant value (e.g., stand-up, sausage, point relascope, etc.).

And plotting the object is as usual...

```
R> plot(btLog.izgFCS, gridCenters=TRUE, showNeedle=TRUE)
```

As mentioned above, because the `chiz` slot contains a list of “InclusionZoneGrid” objects, for each grid cell within the inclusion zone, or NA for grid cells outside the zone, we can step through the internal cells one at a time, looking at summaries or plotting them. One way to do this would be the following...

Figure 7: A “csFullInclusionZoneGrid” object based on a “sausageIZ” object.

```
R> cdx = ifelse(is.na(btLog.izgFCS@chiz), FALSE, TRUE)
R> csl = btLog.izgFCS@chiz[cdx]
R> length(csl)
```

```
[1] 245
```

```
R> sapply(csl[1:4], class)
```

```
           izgCS.34           izgCS.35           izgCS.36           izgCS.37
"InclusionZoneGrid" "InclusionZoneGrid" "InclusionZoneGrid" "InclusionZoneGrid"
```

Again, we could then plot the slivers we are interested in, stepping through to see how the chainsaw method slices the log up for each individual grid cell.

8 Example: The “pointRelascopeIZ” Class

Here we present an example for the point relascope sampling method (Gove et al. 1999, Gove et al. 2001)...

```
R> (angle = .StemEnv$rad2Deg(2*atan(1/2)))
```

```
[1] 53.130102
```

```
R> prs.as = pointRelascope(angle, units='metric')
R> prs.iz = pointRelascopeIZ(dlogs@logs$log.1, prs=prs.as)
R> (izgPRS = izGrid(prs.iz, btr))
```

```
Object of class: InclusionZoneGrid
```

```
-----
pointRelascopeIZ inclusion zone grid object

Figure 8: A “InclusionZoneGrid” object based on a “pointRelascopeIZ” object showing that the stem and inclusion zone are covered by the bounding grid.

9 Example: The “perpendicularDistanceIZ” Class

Here we present an example for the perpendicular distance sampling method (Williams and Gove 2003, Williams et al. 2005, Ducey et al. 2008), this example happens to be for volume estimation. Please note that, because we know the log’s true volume from simulation, we can in fact estimate

all the other attributes for the log. Normally, however, we do not know the true volume from field measurements, so we would only be able to estimate volume under “canonical” PDS, and would use the “omnibus” variant PDS given in the next section to estimate these other quantities...

```
R> pdsmet = perpendicularDistance(kpds=50, units='metric')
R> iz.pds = perpendicularDistanceIZ(dlogs@logs$log.1, pdsmet)
R> (izgPDS = izGrid(iz.pds, btr))
```

```
Object of class: InclusionZoneGrid
```

```

Figure 9: A “InclusionZoneGrid” object based on a “perpendicularDistanceIZ” object showing that the stem and inclusion zone are covered by the bounding grid.

As noted in *The InclusionZone Class* vignette, the inclusion zone for PDS is developed directly from the dataframe in the `taper` slot of the “downLog” object. It can be seen here that if that taper approximation is poor because it uses too few points, it has the potential to exclude grid cells that would otherwise normally be included. This in turn could lead to unexpected “simulation bias” in the sampling surface result (the same thing can happen from using too large a grid cell). Thus, it is fairly important to use a good number of log sections in the taper dataframe to avoid this possibility.

10 Example: The “omnibusPDSIZ” Class

An extension to “canonical” PDS presented in the previous section and given by [Ducey et al. \(2008\)](#), allows one to estimate any attribute on the log and is sometimes referred to as “omnibus” PDS. Because this method uses stem measurements perpendicular to the sample point to form the

estimates, it has varying height surface in each case, except that for the variable we use for the PPS selection of the log¹...

¹Note that if log selection is with PP to volume, then since both biomass and carbon are simply scaled versions of volume, their surfaces will also be constant.

Figure 10: A “InclusionZoneGrid” object based on a “omnibusPDSIZ” object showing the variable height sampling surface for coverage area.

11 Example: The “distanceLimitedMCIZ” Class

Here we interject a method that is not a PDS variant, but we introduce it now because it is used in the distance limited PDS method presented in the next section. The inclusion zone is covered in *The “InclusionZone” Class* vignette, and the surface will be constant only for log length and density. An example follows...

```
R> dlsMet = distanceLimited(3, units='metric')
R> iz.dlmcs = distanceLimitedMCIZ(dlogs@dlogs$log.1, dls=dlsMet)
R> (izgDLMCS = izGrid(iz.dlmcs, btr))

Note from the summary output that the surface is indeed variable for all attributes other than Density and Length. This is illustrated for biomass in Figure 11.

12 Example: The “distanceLimitedPDSIZ” Class

This class, as explained in *The “InclusionZone” Class* vignette, is a hybrid sampling method that restricts the maximum width of the PDS inclusion zone, effectively truncating the search distance for logs. The “hybrid” effect comes from the fact that the inclusion zone can have one of three

Figure 11: A “InclusionZoneGrid” object based on a “distanceLimitedMCIZ” object showing the variable height sampling surface for biomass.

variations: *(i)* the inclusion zone is all PDS, *(ii)* the inclusion zone is all DLMCS, or *(iii)* it is a combination of the two. This flexibility can make things a bit messy, however. We again define two different protocols within this method. First, “canonical” DLPDS uses DLMCS for the truncated portion of the inclusion zone and canonical PDS for the section that is treated as a normal PDS sample.² In the second protocol, we substitute omnibus PDS for any section that is to be sampled with PDS, and refer to this as “omnibus” DLPDS. Note that the difference is entirely based on the protocol for the PDS component (if any) for each log. The PDS component of the inclusion zone can, therefore, be either constant or variable depending on the PPS selection strategy (volume, surface area or coverage area) and the particular attribute we are estimating (refer to the last few sections for more information).

²Of course, in field applications, this method is limited to sampling only for the PPS selection variable in the PDS component for the same reasons as described above.

```
R> iz.dlpds = distanceLimitedPDSIZ(dlogs@logs$log.1, pds=pdsmet, dls=dlsMet)
R> (izgDLPDS = izGrid(iz.dlpds, btr))

y	17.5	25.5

```
R> plot(izgDLPDS, estimate='biomass', showPDSPart=TRUE)
```

Figure 12 shows³ the two inclusion zones in the hybrid region. Since biomass is a scaled version of volume (the PPS selection variable), the PDS component surface is constant as in Figure 9. The DLMCS component is seen to be variable, however, just as the surface generated in Figure 11. Now

³The log is randomly generated with each run of this document, and so differs with each creation, but the parameters are chosen such that it should show the two zones of case (iii).

Figure 12: A “InclusionZoneGrid” object based on a “distanceLimitedPDSIZ” object showing the variable height sampling surface for biomass.

we are able to see why this is a hybrid scheme more clearly. Note also from the object summary that the combination of the two types of inclusion zone objects makes all of the attributes variable in case (iii), since DLMCS will always produce a variable height surface for biomass. If we had chosen either length or density, then the surface would have been constant within each of the sub areas.

13 Example: The “omnibusDLPDSIZ” Class

Omnibus PDS is the final PDS-based method. Again, this is the same as canonical DLPDS with the exception that omnibus PDS is employed within the PDS component of the inclusion zone, if any. This method will be more appropriate for most field applications since one is able to estimate any attribute shown in [Ducey et al. \(2008\)](#). The resulting surface will be variable as described in the sections for the individual component methods above.

```
R> iz.odlpds = omnibusDLPDSIZ(dlogs@logs$log.1, pds=pdsmet, dls=dlsMet)
R> (izgODLPDS = izGrid(iz.odlpds, btr))

y 17.5 25.5
```

```
R> plot(izgODLPDS, estimate='surfaceArea', showPDSPart=TRUE)
```

It may be difficult to see in Figure 13, but the surface is actually slightly convex from butt to tip, because it varies in the reverse sense for each of the two components; i.e., larger near the butt for DLMCS, but larger near the tip for omnibus PDS.

Figure 13: A “InclusionZoneGrid” object based on a “omnibusDLPDSIZ” object showing the variable height sampling surface for surface area.

14 Using `plot3D`

The `plot3D` generic was extended to handle objects of class “InclusionZoneGrid”. Its use is simple, just remember to use the `estimate` argument to specify the desired surface attribute to be rendered...

```
R> plot3D(izgODLPDS, estimate='surfaceArea')
```

Figure 14: Representation of the sampling surface (via an “InclusionZoneGrid” object) for a single log sampled with “omnibusDLPDS”.
